Please replace the title with:

21 PROBE CONSTRUCTION USING A RECESS

Please amend the abstract as follows:

C2 ~~A substrate, preferably constructed of a ductile material and a tool having the desired shape of the resulting device for contacting contact pads on a test device is brought into contact with the substrate. The tool is preferably constructed of a material that is harder than the substrate so that a depression can be readily made therein. A dielectric (insulative) layer, that is preferably patterned, is supported by the substrate. A conductive material is located within the depressions and then preferably lapped to remove excess from the top surface of the dielectric layer and to provide a flat overall surface. A trace is patterned on the dielectric layer and the conductive material. A polyimide layer is then preferably patterned over the entire surface. The substrate is then removed by any suitable process. A method of constructing a probe which includes providing a substrate and creating a first substantially asymmetrical recess within the substrate. A conductive material is located within the recess and a conductive trace is electrically connected with the conductive material. A membrane supports the conductive trace, wherein the conductive material is located between the membrane and the substrate. The substrate is removed from the conductive material.~~
